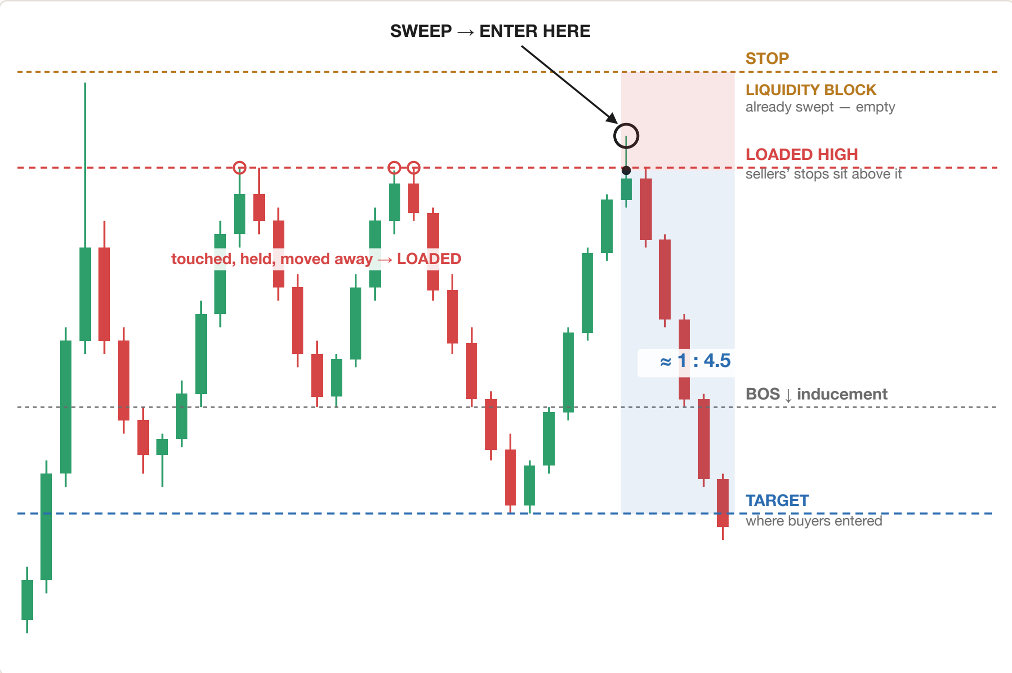
The same event, two different entries

Both panels are SHORTS. Both are built on one sweep of a level that had orders resting behind it. What differs is WHEN you get in.

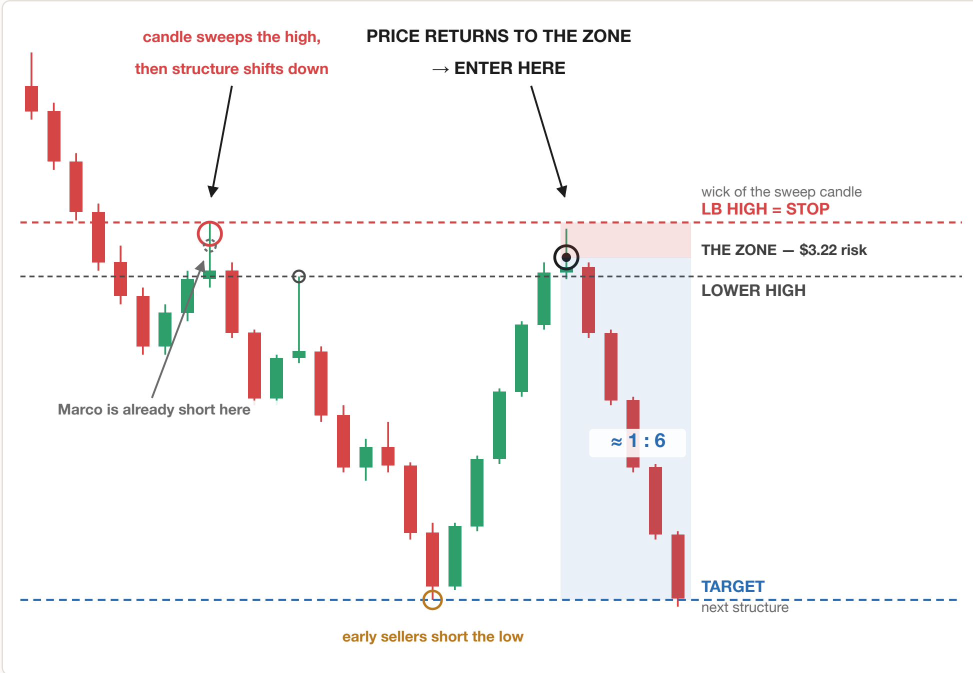
MARCO — enter ON the sweep

"We enter as soon as the liquidity is taken. We don't need the imbalance. We don't need the exact top."



YOURS — enter on the PULLBACK

You let the sweep confirm, let price run, then sell the retrace back into the gap it left behind.

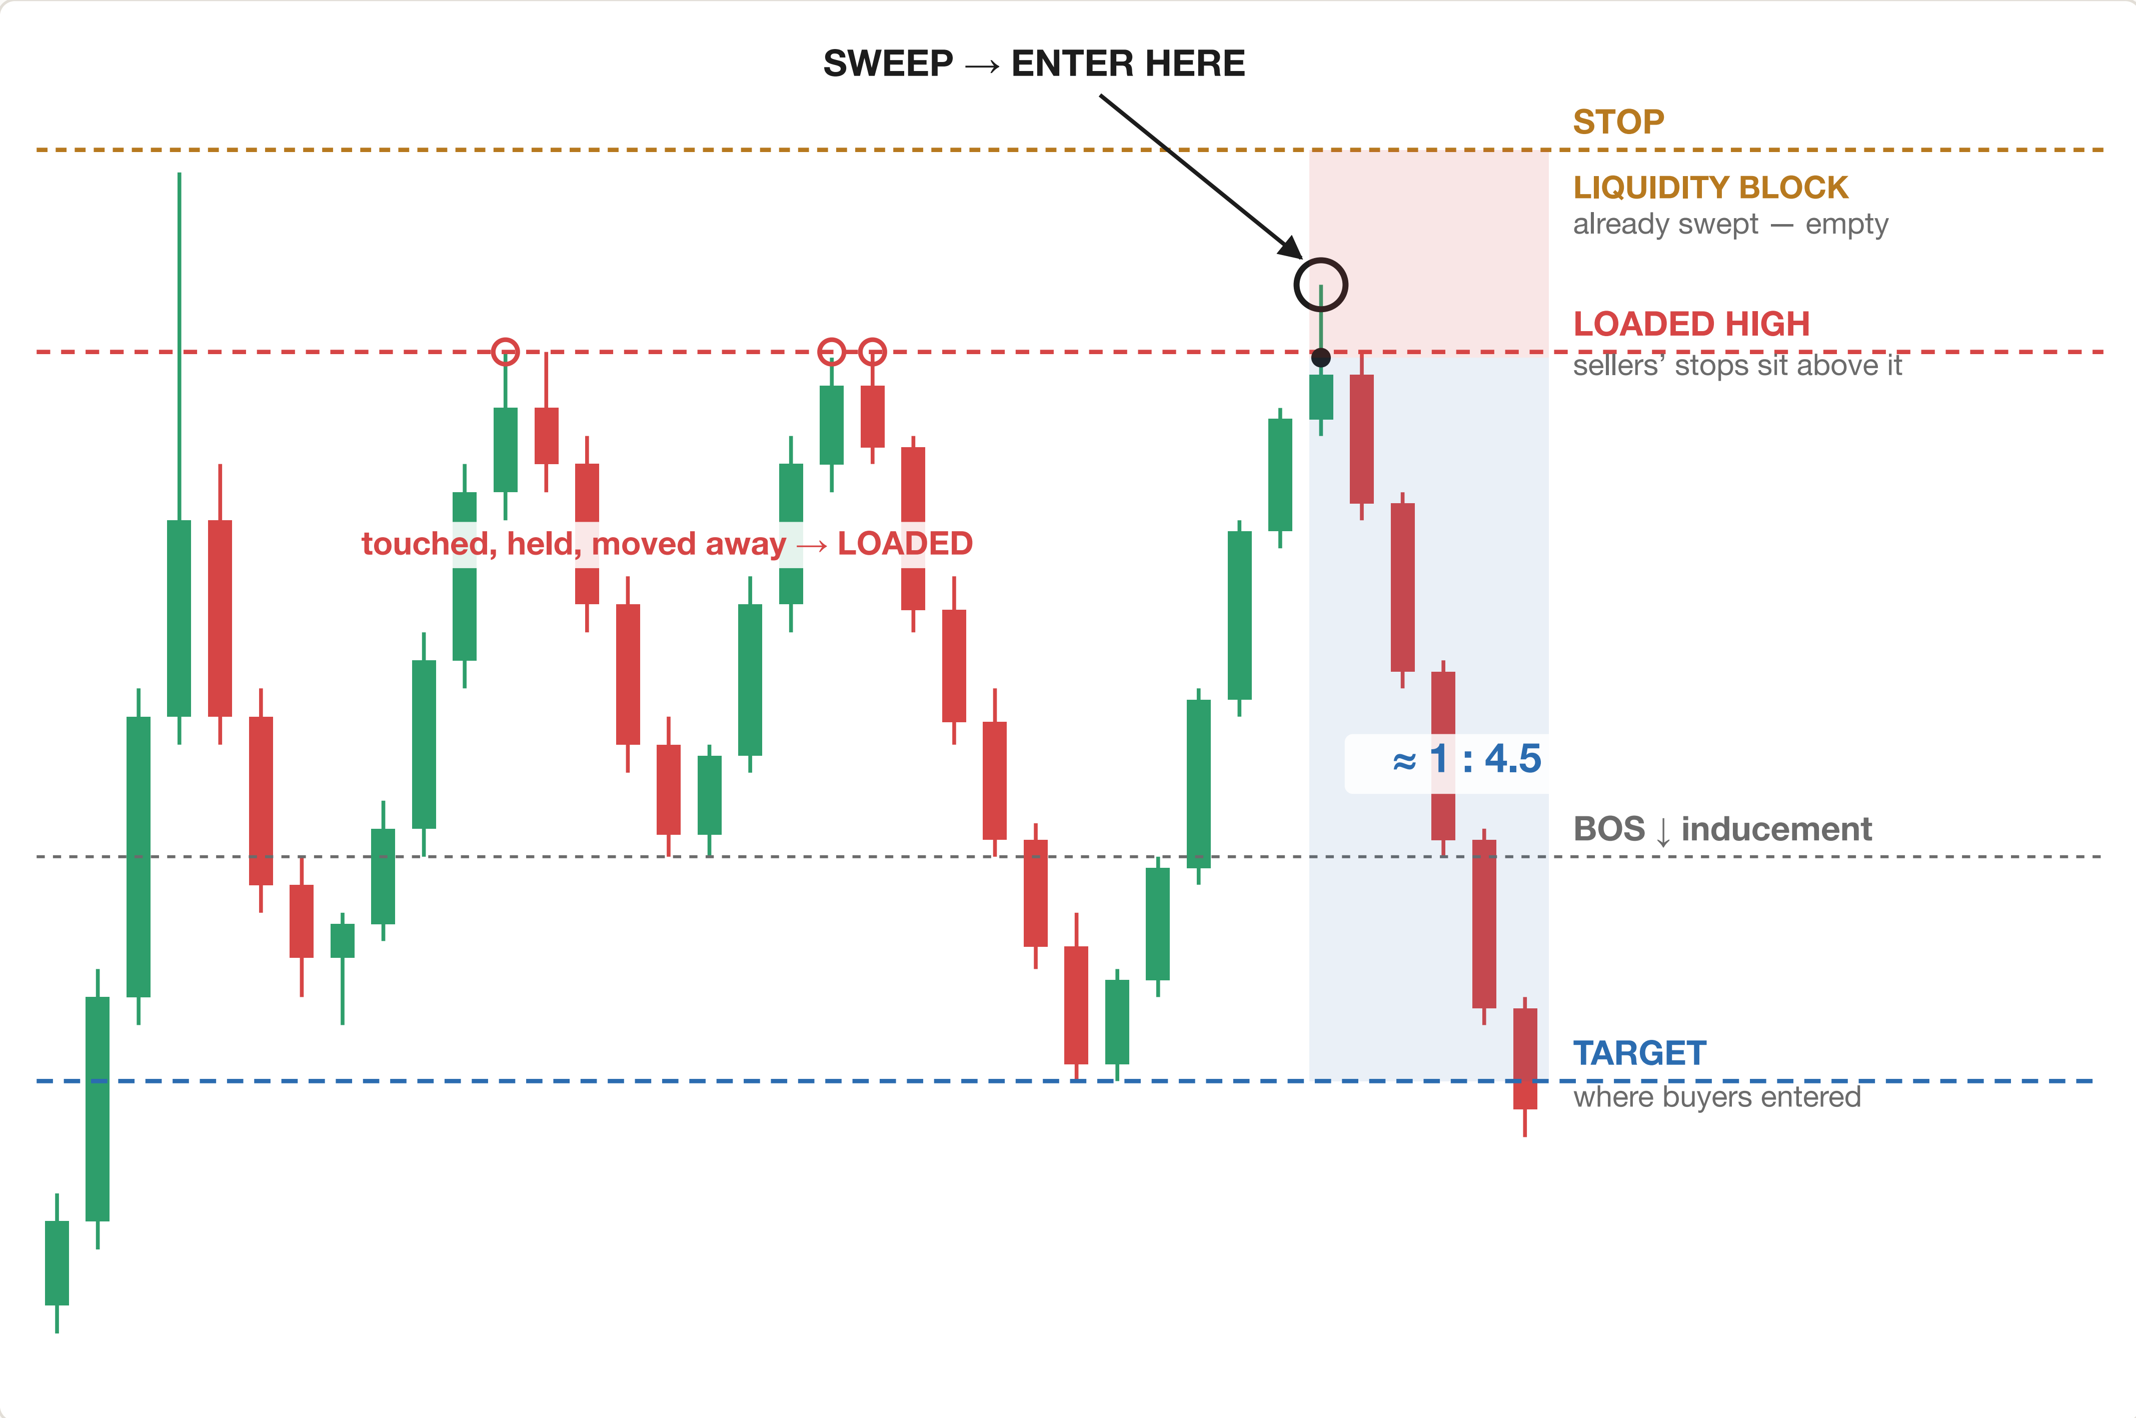


Where they agree, and where they don't

	MARCO	YOURS
What arms it SAME	A high that price returned to, respected, and moved away from. Orders rest behind it.	A candle sweeps a high and structure shifts. Same event — you just demand the shift as proof.
Where the stop goes SAME	Above the liquidity block — an area already swept, so nothing is left to drag price back.	Above the wick of the sweep candle. Tighter, and usually the same idea.
WHEN you get in DIFFERENT	At the extreme, the instant the level is taken. Best price, but you are catching the knife.	On the retrace into the gap between two lower highs. Worse price, but the move already proved itself.
What you give up DIFFERENT	Some sweeps just keep going. Wider stop, and more entries that fail on the spot.	Price often never comes back. You miss the trade and watch it run without you.
Minimum reward CHECK THIS	1:3 floor. He skips anything under it.	You said 1:2. Our 8-year test: below 2R the edge over random disappeared.

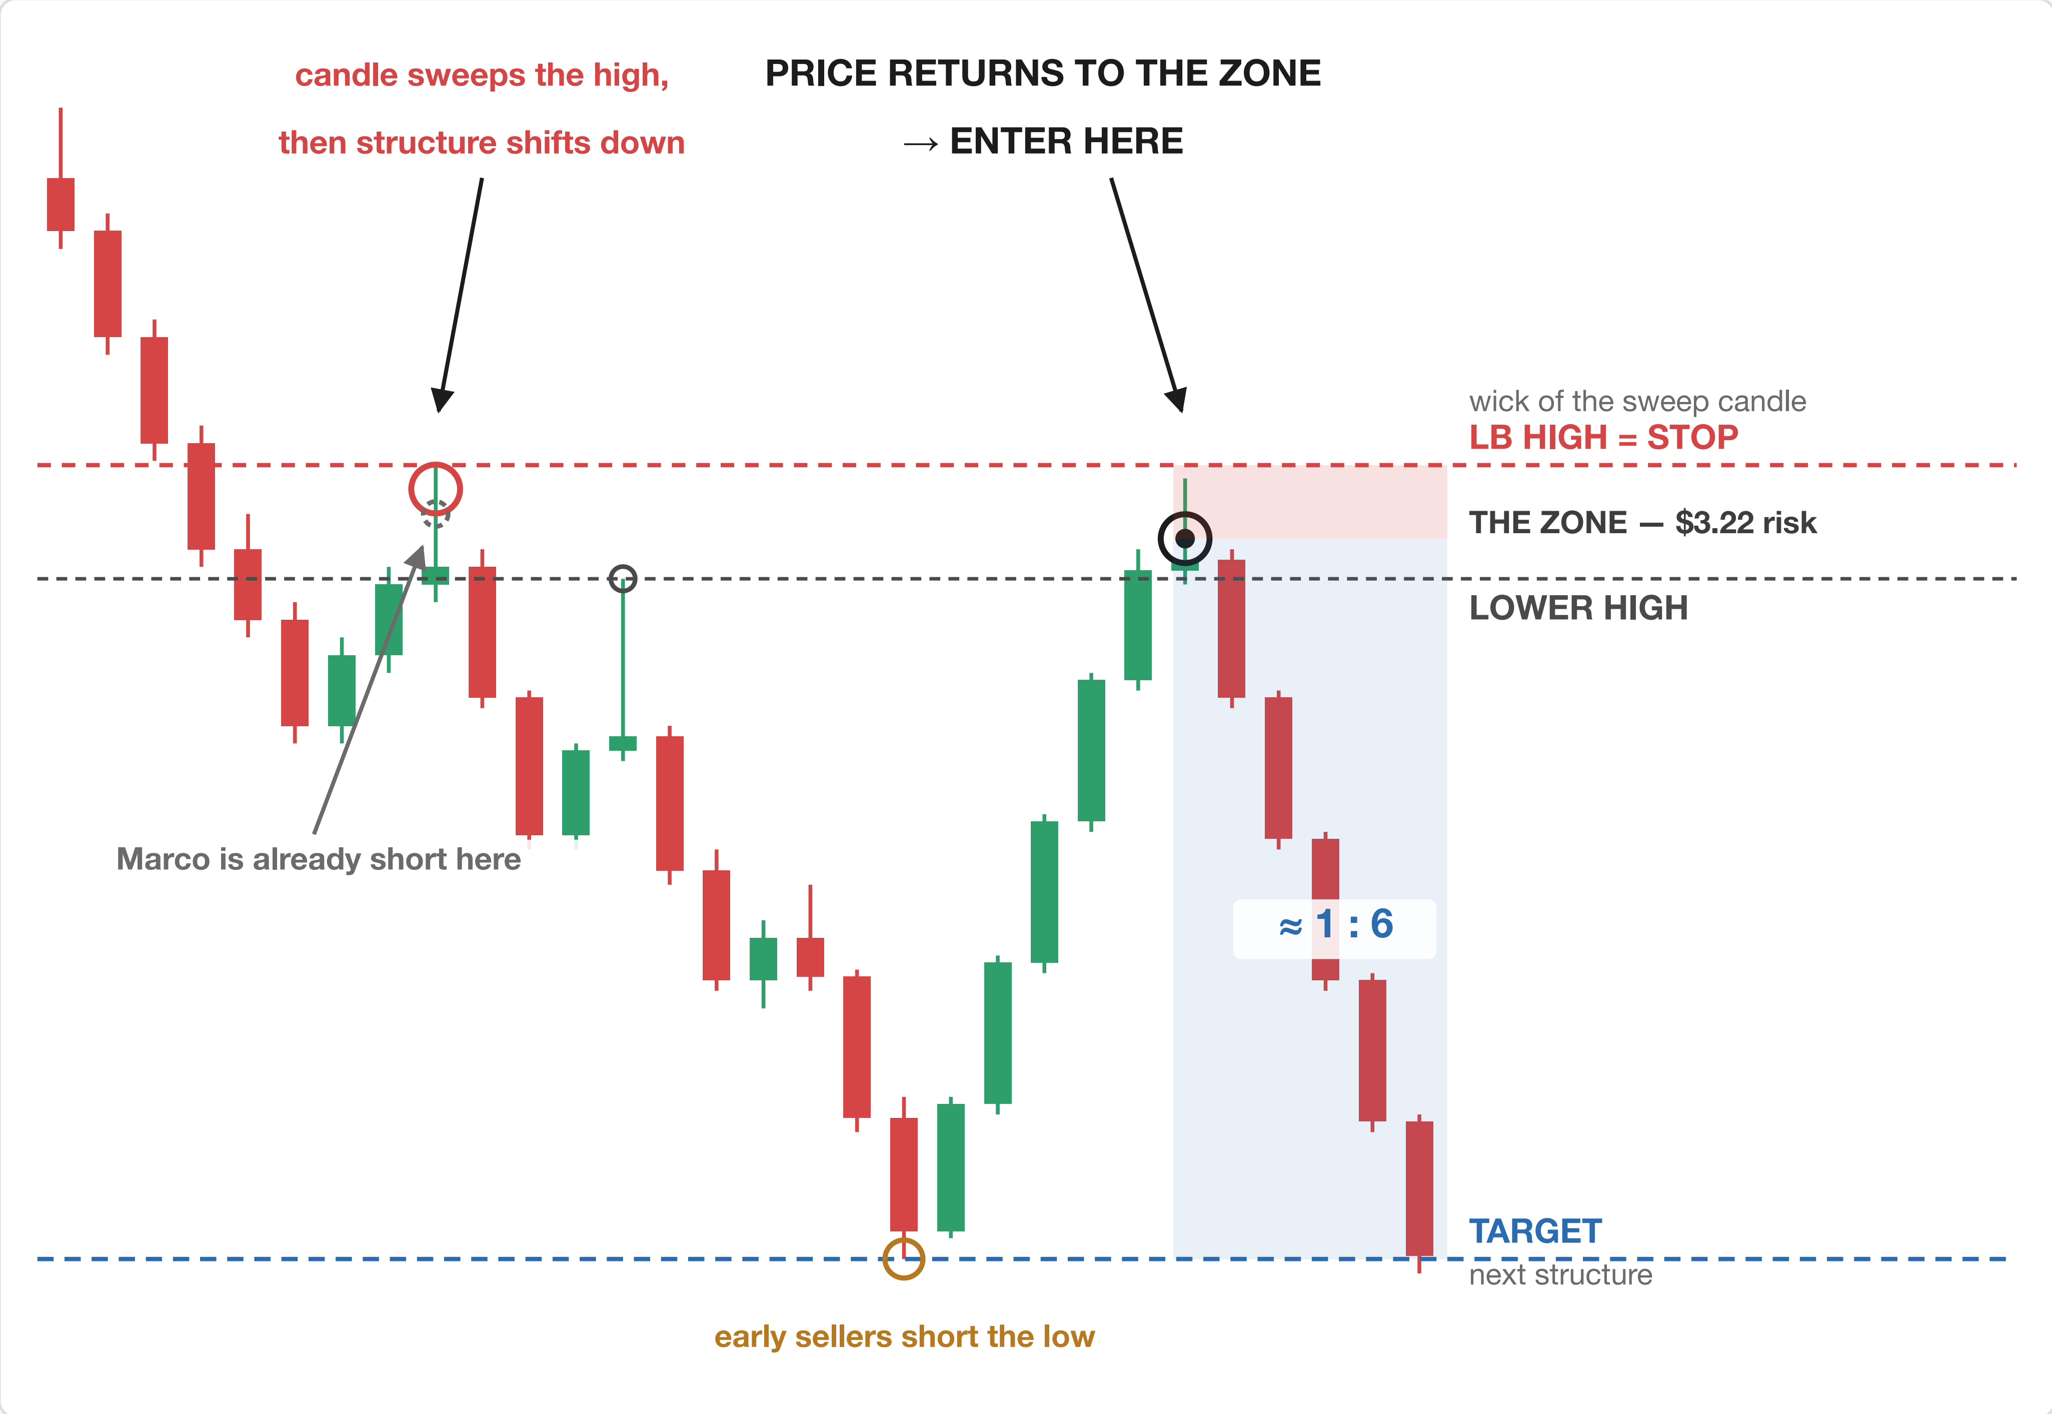
MARCO — enter ON the sweep

“We enter as soon as the liquidity is taken. We don’t need the imbalance. We don’t need the exact top.”



YOURS — enter on the PULLBACK

You let the sweep confirm, let price run, then sell the retrace back into the gap it left behind.



Where they agree, and where they don’t

Both models arm on the same event. The split is timing, and everything it costs you.

Minimum reward CHECK THIS	1:3 floor. He skips anything under it.	You said 1:2. Our eight-year test found the edge over random disappeared below 2R.

Three things that have to be pinned down before this can be coded

1. **What counts as “the market shifts”?**
   After your sweep candle there is an iBOS. Is the shift the internal break, the swing break, or just the next lower low? This decides how many blocks ever arm.
2. **Is the early-sellers low required, or just what usually happens?**
   If it is required it is a gate and cuts the trade count. If it is descriptive it is scenery.
3. **Where in the zone do you fill?**
   Limit at the far edge is the best R and misses most often. Limit at the near edge fills more and pays less. Market on touch sits between them. All three are testable; they are not the same strategy.

Charts are schematic. The right-hand panel follows a real XAUUSD short taken 13 Aug 2026 (block high 4373.88, zone floor 4370.66, target 4351.41). Marco = Inter Equity Trading.
